¾ Suspensions having particle sizes of greater than about 1micron in diameter are called as coarse suspensions. ¾ Suspensions are the biphasic colloidal dispersions of nanosized drug particles stabilized by surfactants. ¾ Size of the drug particles is less than 1mm.

The movement of the suspension is the stroke, and the amount of stroke that is used for shock absorption is the travel. A suspension fork or rear shock are comprised of three main elements: ¢ spring - Manages the majority of energy created by impact to isolate the bicycle/rider from shock and vibration.

Suspensions may occur on any part of the chord (root, third, fifth, or seventh), but they always resolve down by step. Ties are optional. A suspension always has three parts: 1.

## **A theory of dilute suspensions - [PDF Document]**

In this paper the results obtained by JEFFERY [3] for the motion of an ellipsoid suspended in a Newtonian fluid are used to formulate a theory of dilute suspensions. We show that this theory can be considered a special case of ERICKSEN'S theory of anisotropic fluids [1, 21].

Chapter 9. Theory of Active Suspensions. David Saintillan and Michael J. Shelley Abstract Active suspensions, of which a bath of swimming microorganisms is a paradigmatic example, denote large collections of individual particles or macro- molecules capable of converting fuel into mechanical work and microstructural stresses.

## **Chapter 9 Theory of Active Suspensions**

The theory was initially formulated for two identical interfaces (symmetric system), which corresponds to the case of the aggregation of identical particles (homoaggregation). This concept was later extended to the two different interfaces (asymmetric system) and aggregation of different particles (heteroaggregation).
